

on int 13h calls which access floppies. After making the changes I was able to successfully upgrade the machine with the bad driver installed.

If this needs to be built, Ericar needs to sync up to the file \dos500\install\lib\disk\newint13.asm and then rebuild the directories LIB, RETAIL, RECOVER and BACKUP.

The change was 2 new lines of asm code and was reviewed by Sriram.

Bob has misquoted me. I informed him that the undocumented call in 3.0, ControlPanelInfo(), would be removed and replaced in 3.1 by SystemParametersInfo(), which *will* be documented. DavidDS and ChrisG can explain why we shouldn't just document ControlPanelInfo() instead of replacing it.

The Windows group has been proactive on these issues. We went to them with the Control Panel hook. We discovered that their tracking would break in 3.1. And it's likely that we didn't actually tell them about the undoc call, but that they discovered it in source code.

This boils down to one question: How long do we keep ControlPanelInfo() around in Windows?

Also, I don't believe anyone over here has described the icon as a "funny thing to want." This is a shell issue; Lisa Cram can best explain our position. (FYI, Logitech has also explicitly requested to supply their own icon.)
