I loaded DR 6 on my own system about a week ago and have been using it since. Although I was unable to get Windows to run in enhanced mode using DR's D+386.SYS, I do run it using MIDOS.SYS, their equivalent to himem. So while I have no UMB support, it doesn't matter much since I use all Win apps. I was also able to run standard mode using MIDOS.SYS.

I haven't had any UAE or crashing problems of note. The only difference, which I haven't tested so I can't confirm, seems to be that printing from Winword 2 is much slower than it was under MS-DOS 5.

In short, I haven't seen any basic kernel incompatibilities.

i played with it for about 45 min this morning. it's quite easy to crash, even hard hang that requires a power cycle. lots of "use's. still has a long way to go stability wise. though they have clearly made a lot of progress since the last drop we had. the workplace shell is usable and win apps do run, mostly. easy to run out of memory doing simple things, and it was on a 9M machine.

one nice thing is that way to config a dos vm. i'll make sure the dos guys have a look.

it's running in chrissh's perf lab. check it out. the nice thing is the way the let you config a dos vm, essentially managing the config.sys in a dialog box.
