You are probably compiling with the -qc switch. Try taking it out.
The __adbused flag is used by the QC debugger, I believe.

  I have a app that when I try to link it with the WLO 0.9 code base gets an
  unresolved reference to __ADBUSED. This is usually resloved to LLIB, but
  appears to be missing from the WLO versions.

  Can any one help with ways to resolve this problem.

  Thanks - Steve

We are being asked to make it impossible to run Windows
3.1 in protected mode under any DPMI server on OS/2 1.x
or 2.x, even though our 3.1 kernel is now a full DPMI
client and IBM has full access to Windows 3.1 source code.

Any proposed schemes should not interfere with the ability
to run under other DPMI implementations.

Any ideas?

| Can you guys do me an additional favor on this and
| follow up with one of the old cruiser guys about
| the tiling issue? Scottlu maybe. This is incredibly
| key.

|
| On further investigation, OS/2 doesn't stand a
| chance of running the current kernels for the
| following reasons:
|
| 1. Selector tiling. This is hard-wired in the kernels
| to be an increment of 8 between successive selectors
| in a selector array. We don't even bother to validate
| this from DPMI. I KNOW this is not 8 in OS/2.
|
| 2. GrowSFTToMax attempts to grow the SFT. There are no
| version checks in the code. I expect it to fail
| (ie fault) under OS/2. We should put a version check
| in this routine and abort the boot under OS/2.(!)
|
| Aaron knows some other gotchas which they would have
| to work around too.
|
| Tony.

I was down at the windows/os2 conference in San Jose
and bumped into MAURICE FULLER.

He currently runs a Windows consulting firm called Synaptix. (its
headquarters are in the U-District)

He wanted me to say hi to you two guys and said he had a fun
time when he was working with you two. He was almost crying.
Well maybe not crying, but he says he misses you two. I don't
know why....
